A review of immunologic mechanisms and new therapies for active systemic lupus erythematosus. We provide an overview of the complex pathophysiology of systemic lupus erythematosus (SLE). A number of recent studies have identified new mechanisms of disease. The autoantigenic repertoire of SLE has expanded to include a growing number of nuclear antigens as well as autoantigens associated with the extracellular matrix and the inner and outer surface of apoptotic cells. Analysis of B and T cell responses revealed a dysregulated Th1 response, including enhanced expression of Th1 cytokines, interferon-gamma and IL-2, and decreased expression of Th2 cytokines, IL-4 and IL-10, and T cell growth factors. Autoantibodies, in particular anti-DNA and anti-Sm, have a number of different functions, including activation of complement, generation of immune complexes, and internalization of IgG. New treatment options have been introduced over the last few years, including novel immunosuppressive agents, including belimumab and B cell depletion therapy. These novel therapies have provided significant new insights into the pathophysiology of SLE, and hold great promise for the future. Super Bowl XLIX is almost here, and now the biggest, coldest Super Bowl party is one step closer to hitting the road. The Big Game will be played at the University of Phoenix Stadium in Glendale, Ariz. on Feb. 1, and the cold and rain have some saying that the game could be canceled. This would mark the third year in a row a Super Bowl has been canceled due to weather. Last year, 2d92ce491b
